Q: Can I have something like Active Record in Python? I want to read and write to a database which is local at the client's machine and connected to a my server. Also, I want to access the data through an API, which will run on a server. At my server I'll check for updates and everytime a row gets updated I want to send the new data to the client, which will then insert the data into the database. Can this be achieved in Python? Or if this can be achieved with Django, is Django a better option to start with? Or would this be a more web language solution? A: What you are looking for is called a "RESTful web service" and is described in full detail here: For your situation: Yes, in Python you can define a simple REST service (i.e. a Python script that returns JSON encoded data). If you are working with Django, then what you are looking for is described here: which suggests the following: One interesting feature is that you can use the 'allow\_json' configuration option to only allow the response to be in JSON format. That way you can write your own scripts using Django without worrying about the type of the responses (otherwise you may end up with the infamous 'Migration InconsistentException'). Please take a look at the tutorial provided above and let me know if it helps. Good luck! {¶ 30} The first assignment of error is overruled. II. ### What's New In?

No, not the National Security Agency, but the Office of Personnel Management (OPM) which is the investigative arm of the federal government. Members of this organization include: The Federal Investigator Team The Federal Employee/Internal Affairs Unit (FEIU) The Office of Special Counsel The U.S. Office of Special Counsel is a special federal agency established by Congress. Its purpose is to protect federal employees from discrimination and retaliation. Congress gave the Office of Special Counsel the authority to settle employee claims of discrimination and retaliation. Q: Avoiding creating a new array to store a value that is in a list, Haskell I am implementing the following functions. `mappend x xs ys = x : mappend xs ys` `mappend (x:xs) (y:ys) = mappend xs ys` `mappend [] ys = ys` `mappend (x:xs) (y:ys) = x : mappend xs ys` So, I am required to implement these functions using two ways: Without creating a new array to store a value that is in a list. Edit: What I really meant by "without creating a new array" is that I am not creating a new list but just storing the value that is already in the list. So, in my opinion, the answer to this question is no. AFAIK the solution should be of type `mappend :: (a -> [b] -> [c]) -> [a] -> [b] -> [c]`. The `a` is the first parameter of `mappend (sums xs ys)` which is a list containing the first element of `xs`, the second element of `xs`, and the second element of `xs`, and so on. The type of the first parameter of `mappend (xs:ys)` is `[(a,b,c)]` Thanks to the comment from Mikolaj, I've been able to solve this without creating a new array as such: `let mappend xs ys = map (\k -> k : (map (-> k+n) ys)) xs` A: The solution is in that type signature. Since you're not implementing a new array but simply operating on the `x` and `y` lists element by element
